

Advanced topics in Markov-chain Monte Carlo

Lecture 2:

Diameters and conductances, liftings, path graph
Part 2/2: Lifting / Examples

Werner Krauth

Metropolis algorithm on path graph (1/4)

- path graph $P_n = (\Omega_n, E_n) \dots$
- vertices \Leftrightarrow sample space $\Omega_n = \{1, \dots, n\}$
- edges $E_n = \{(1, 2), \dots, (n-1, n)\} \Leftrightarrow$ non-zero P_{ij}
- one-d n -site lattice without pbc.
- stationary distribution $\pi = \{\pi_1, \dots, \pi_n\} \Leftrightarrow$ GBC.
- **Phantom vertices** 0 and $n+1$ with $\pi_0 = \pi_{n+1} = 0$, and
- **Phantom edges** $(0, 1)$ and $(n, n+1)$.

Metropolis algorithm:

- 1 From vertex $i \in \Omega$ choose $j = i \pm 1$ with probability $1/2$
- 2 accept $i \rightarrow j$ with probability $\min(1, \pi_j/\pi_i)$
- 3 else stay at i .
- 4 NB: **Phantoms** are nice

Metropolis algorithm on path graph (2/4)

- Checking detailed balance ($\pi_i P_{ij} = \pi_j P_{ji}$):
- Checking global balance ($\sum_i \pi_i P_{ij} = \pi_j$):

$$\underbrace{\pi_i - \frac{1}{2} \min(\pi_i, \pi_{i-1}) - \frac{1}{2} \min(\pi_i, \pi_{i+1})}_{\text{curved arrow from } i \text{ to } i}$$

$$\boxed{i-1} \begin{array}{c} \xrightarrow{\frac{1}{2} \min(\pi_{i-1}, \pi_i)} \\ \xleftarrow{\frac{1}{2} \min(\pi_i, \pi_{i-1})} \end{array} \boxed{i} \begin{array}{c} \xrightarrow{\frac{1}{2} \min(\pi_i, \pi_{i+1})} \\ \xleftarrow{\frac{1}{2} \min(\pi_{i+1}, \pi_i)} \end{array} \boxed{i+1}$$

- Irreducibility **OK**
- Aperiodicity **OK, thanks to boundaries**

Metropolis algorithm on path graph (3/4)

- Constant: $\pi_i = \frac{1}{n} \forall i \in \Omega$.
Conductance $\Phi = \mathcal{O}(1/n)$.
- Square wave: $\pi_{2k-1} = \frac{2}{3n}, \pi_{2k} = \frac{4}{3n}$.
Conductance $\Phi = \frac{2}{3n}$ (for $n \rightarrow \infty$).
- V-shaped: $\pi_i = \text{const} \left| \frac{n+1}{2} - i \right| \forall i \in \Omega$, where $\text{const} = \frac{4}{n^2}$.
Conductance $\Phi = \frac{2}{n^2}$.

NB: Graph diameter n .

NNB: π normalized.

NNNB: Bottleneck between $i = \frac{n}{2}$ and $j = \frac{n}{2} + 1$.

Metropolis algorithm on path graph (4/4)

- Constant: $\pi_i = \frac{1}{n} \forall i \in \Omega$.
Conductance $\Phi = \mathcal{O}(1/n)$.
Mixing time $\mathcal{O}(n^2)$. **Markov chain is transport-limited.**
- Square wave: $\pi_{2k-1} = \frac{2}{3n}, \pi_{2k} = \frac{4}{3n}$.
Conductance $\Phi = \frac{2}{3n}$ (for $n \rightarrow \infty$).
Mixing time $\mathcal{O}(n^2)$. **Markov chain is transport-limited.**
- V-shaped: $\pi_i = \text{const} \left| \frac{n+1}{2} - i \right| \forall i \in \Omega$, where $\text{const} = \frac{4}{n^2}$.
Conductance $\Phi = \frac{2}{n^2}$.
Mixing time $\mathcal{O}(n^2 \log n)$. **Markov chain is conductance-limited (up to a log).**
NB: Mixing time in \mathcal{S} is $\mathcal{O}(n^2)$.

- Markov chain $\Pi \Leftrightarrow$ Lifted Markov chain $\hat{\Pi}$
- Ω (sample space) $\Leftrightarrow \hat{\Omega}$ (lifted sample space)
- P (transition matrix) $\Leftrightarrow \hat{P}$ (lifted transition matrix)
- **Condition 1:** sample space is copied (“lifted”), π preserved

$$\pi_v = \hat{\pi} \left[f^{-1}(v) \right] = \sum_{i \in f^{-1}(v)} \hat{\pi}_i,$$

- **Condition 2:** flows are preserved

$$\underbrace{\pi_v P_{vu}}_{\text{collapsed flow}} = \sum_{i \in f^{-1}(v), j \in f^{-1}(u)} \overbrace{\hat{\pi}_i \hat{P}_{ij}}^{\text{lifted flow}}.$$

- Usually: $\hat{\Omega} = \Omega \times \mathcal{L}$, with \mathcal{L} a set of lifting variables σ

- **Condition 1:** sample space is copied (“lifted”), π preserved

$$\pi_v = \hat{\pi} \left[f^{-1}(v) \right] = \sum_{i \in f^{-1}(v)} \hat{\pi}_i,$$

- **Condition 2:** flows are preserved

$$\underbrace{\pi_v P_{vu}}_{\text{collapsed flow}} = \sum_{i \in f^{-1}(v), j \in f^{-1}(u)} \overbrace{\hat{\pi}_i \hat{P}_{ij}}^{\text{lifted flow}}.$$

- Lifting does not increase the conductance (TD).

Lifting on the path graph (1/4)

Probability distribution $\pi = (1/n, \dots, 1/n)$ (Diaconis et al. 2000)

- “Collapsed” Markov chain:

- “Lifted” Markov chain $\hat{\Omega} = \Omega \times \{-, +\}$:

Lifting on the path graph (2/4)

Probability distribution $\pi = (1/n, \dots, 1/n)$ (Diaconis et al. 2000)

- “Lifted” Markov chain $\hat{\Omega} = \Omega \times \{-, +\}$:

- Two-step version

Lifting on the path graph (3/4)

Probability distribution $\pi = (1/n, \dots, 1/n)$ (Diaconis et al. 2000)

- “Lifted” Markov chain $\hat{\Omega} = \Omega \times \{-, +\}$:

- Two-step version

- Analyze, then generalize the behavior at the boundaries

Lifting on the path graph (4/4)

- “Lifted Markov chain: **Transport**”

- “Lifted Markov chain: **Resampling**”

- Resampling can often be dropped

Lifting and global balance

- Flow into configuration $(x, +)$ (transport):

$$(x-1, +) \rightarrow (x, +) \quad \mathcal{A}_x^+ = \min(\pi_{x-1}^+, \pi_x^+)$$

$$(x, -) \rightarrow (x, +) \quad \mathcal{R}_x^+ = \pi_x^- - \min(\pi_{x-1}^-, \pi_x^-)$$

- Flow into configuration $(x, +)$ (resampling):

$$(x, +) \rightarrow (x, +) \quad \mathcal{L}_x^{++} = (1 - \lambda)\pi_x^+ = \frac{1}{2}(1 - \lambda)\pi(x)$$

$$(x, -) \rightarrow (x, +) \quad \mathcal{L}_x^{-+} = \lambda\pi_x^- = \frac{1}{2}\lambda\pi(x)$$

Lifting and mixing

- The V-shaped stationary distribution is an ideal model to test the lifted Metropolis algorithm.
- It has conductance $\mathcal{O}(2/n^2)$, so mixing at least $\sim n^2$
- Collapsed Metropolis: $t_{\text{mix}} = \mathcal{O}(n^2 \log n)$
- Lifted Metropolis: $t_{\text{mix}} = \mathcal{O}(n^2)$
- Lifted Metropolis (restricted to $S = \{1, \dots, \frac{n}{2}\}$)
 $t_{\text{mix}}^{\text{restricted}} = \mathcal{O}(n)$ with TVD decreasing to $\frac{1}{2}$.
